# Lab 1: Introduction to R

Feng Qiu, Liyuan Xuan

## 0.1 Download and Install

#### • R

R is a free software environment for statistical computing and graphics. To download, go to CRAN and select the installer for your operating system (Windows, Mac, or Linux).

## • RStudio

RStudio is a user-friendly application that helps you write in R and enhances your programming experience. To download, visit this website and select the installer for your operating system.

After R and RStudio are installed, we will only need to use RStudio for this and future labs. The default RStudio layout has three panes: **Console**, **Environment**, and **Output**.

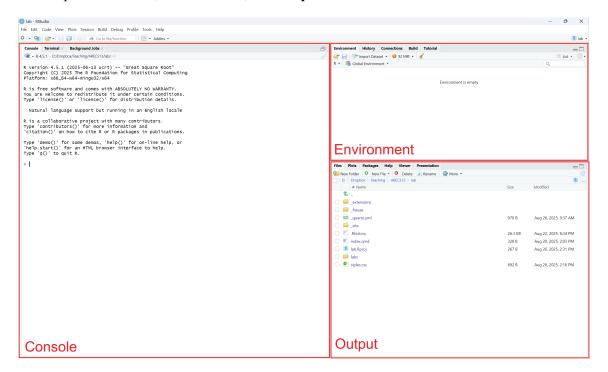

Figure 1: screenshot of RStudio

You can customize your RStudio working environment via Tools > Global Options in the top menu bar.

## 0.2 Working Directory

The working directory is a folder path on your computer that sets the default location for files you read into R or save out of R. Think of it as a little "flag" on your computer tied to your project.

• To find your current working directory, type the code below in your Console pane and press *Enter*.

getwd()
[1] "D:/Dropbox/Teaching/AREC513/Fall2025/PDF\_only/lab1"

• To change your current working directory, you can

1. Use the code below

setwd("C:/Program Files")

In R, file paths are separated by **forward slash** /, not backward slash \. The full path needs to be wrapped with the double quotations " "

- 2. Use the top menu bar Session > Set Working Directory > Choose Directory
- 3. To set a default working directory, go to Tools > Global Options > General > Default working directory

## 0.3 R Basics

#### 0.3.1 Calculations

1 + 1

[1] 2

5 \* 6

[1] 30

2 ^ 4

[1] 16

(8 + 5 \* 6 / 3) / 2

[1] 9

## 0.3.2 Creating Objects

```
a <- 5 * 6
a

[1] 30

b <- 8 + a / 3
b

[1] 18

c <- "AREC 513"
c
```

[1] "AREC 513"

In RStudio, you can use the shortcut Alt + - (hyphen) to write the assignment operator <-.

## 0.3.3 Data Types

[1] TRUE

There are four main data types in R we will use in the labs: numeric, integer, logical, and character.

• Numeric data, also known as quantitative data

```
is.numeric(b) # test if the object "b" is numeric
[1] TRUE
```

• Integer data, stores whole numbers without decimals

```
d <- 8L  # to generate integer variable, add "L" after the number
is.integer(d)</pre>
```

• Logical data, stores only TRUE or FALSE

```
e <- TRUE
is.logical(e)
[1] TRUE</pre>
```

• Character data, stores text strings

```
is.character(c)
[1] TRUE
```

```
? Tip
```

You can also use class() to check the class of an object. For example, try class(a).

To convert your objects to a specific type, use as.numeric(), as.integer(), as.logical(), or as.character().

#### 0.3.4 Data Structures

When analyzing data, you rarely deal with objects that store one single value or datasets with one single variable. This section discusses some common data structures.

#### **0.3.4.1** Vectors

## 0.3.4.1.1 Create a Vector

Vectors play a crucial role in R, R is a vectorized language. A vector is a collection of values/elements, all of the same type. We can use the function c() to create a vector, which means "combine".

```
grades_1 <- c(75, 76, 77, 78, 79, 80, 81, 82, 83, 84)
grades_1

[1] 75 76 77 78 79 80 81 82 83 84

grades_2 <- c(75:84) # to generate continuous values from 75 to 80, you can use ":" directly.
grades_2</pre>
```

[1] 75 76 77 78 79 80 81 82 83 84

```
names <- c("Marshall", "Ruby", "Peppa", "George", "Suzy", "Danny",</pre>
          "Pedro", "Rebecca", "Rubble", "Ryder", "Max", "Chase")
names
 [1] "Marshall" "Ruby"
                                               "Suzy"
                                     "George"
                                                          "Danny"
                          "Peppa"
 [7] "Pedro"
               "Rebecca"
                          "Rubble"
                                     "Ryder"
                                               "Max"
                                                          "Chase"
0.3.4.1.2 Vector Operations
{\tt grades\_1} + {\tt 5} # operations apply to each element in the vector
 [1] 80 81 82 83 84 85 86 87 88 89
grades_1 * 2
 [1] 150 152 154 156 158 160 162 164 166 168
sqrt(grades_1)
 [1] 8.660254 8.717798 8.774964 8.831761 8.888194 8.944272 9.000000 9.055385
 [9] 9.110434 9.165151
grades_1 >= 78
 0.3.4.1.3 Factor Vectors
Factor variables are important when building statistical models. There are two types of factor variable,
   • nominal: categorical variable with no inherent order among the categories
jbp <- c("poor", "excellent", "fair", "poor", "good") # create a nominal job performance vector
```

"good"

"poor"

jbp

[1] "poor"

"excellent" "fair"

```
class(jbp)
[1] "character"

jbp.1 <- as.factor(jbp)  # converting your character vector to factor
jbp.1

[1] poor excellent fair poor good
Levels: excellent fair good poor

class(jbp.1)
[1] "factor"</pre>
```

• ordinal: categorical variable with a defined ranking among the categories

```
# create a job performance vector, that is nominal
jbp.2 <- factor(jbp, levels = c("poor", "fair", "good", "excellent"))  # assigning an ordinal ranking
jbp.2

[1] poor excellent fair poor good
Levels: poor fair good excellent</pre>
```

#### **0.3.4.1.4** Subset Vectors and Select Elements

To subset a vector or select certain elements from a vector, we use the square brackets [].

## · By Position

```
grades_1[1]  # select the 1st element

[1] 75

grades_1[-2]  # exclude the 2nd element

[1] 75 77 78 79 80 81 82 83 84
```

```
# select elements 3 to 5
 grades_1[3:5]
  [1] 77 78 79
 grades_1[c(1,3,5)] # select the 1st, 3rd, and 5th elements
  [1] 75 77 79
• By Condition
 grades_1[grades_1 >= 78]
                                         # select grades_1 that are equal or above 78
  [1] 78 79 80 81 82 83 84
 grades_1[grades_1 != 78]
                                         # select grades_1 that do not equal to 78
  [1] 75 76 77 79 80 81 82 83 84
 jbp.2[jbp.2 %in% c("poor", "fair")]
                                         # select job performance that is "poor" or "fair"
  [1] poor fair poor
 Levels: poor fair good excellent
    ? Tip
```

#### **0.3.4.2** Matrices

A matrix is a collection of data elements arranged in a two-dimensional rectangular layout. The elements of a matrix must be of the same type of data. Matrices are commonly used in mathematics and statistics. Math matrices and R matrices are different concepts. Matrices in R are broader.

If you wish to apply multiple conditions, the common operators are & (Shift + 7) for AND and | (Shift

+\) for OR. Try grades\_1[grades\_1 >= 78 & grades\_1 != 80].

```
ma.1 <- matrix(1:15, nrow = 5, ncol =3)
ma.1
     [,1] [,2] [,3]
[1,]
                 11
[2,]
        2
             7
                 12
[3,]
                 13
[4,]
             9
                 14
[5,]
        5
            10
                 15
```

```
ma.2
     [,1]
                [,2]
[1,] "Marshall" "Pedro"
[2,] "Ruby"
                "Rebecca"
[3,] "Peppa"
                "Rubble"
[4,] "George"
                "Ryder"
[5,] "Suzy"
                "Max"
[6,] "Danny"
                "Chase"
Since matrices are two-dimensional, to subset or select elements from a matrix using [], you need to define row
and/or column index in [ROW, COL].
ma.1[2, ] # select all elements in the 2nd row of ma.1
[1] 2 7 12
ma.1[, 2] # select all elements in the 2nd column of ma.1
[1] 6 7 8 9 10
ma.1[2, 2] # select the element in row 2 and column 2 of ma.1
[1] 7
ma.2[3, 2] # select the element in row 3 and column 2 of ma.2
[1] "Rubble"
```

## 0.3.4.3 Arrays

ma.2 <- matrix(names, nrow = 6, ncol = 2)</pre>

In R, arrays are the data objects that can store data in more than two dimensions. Data need to be the same type.

```
array.1 <- array(1:24, dim = c(2, 3, 4))  # 2 rows * 3 columns * 4 matrices
array.1</pre>
```

```
, , 1
    [,1] [,2] [,3]
[1,]
           3
[2,]
, , 2
    [,1] [,2] [,3]
[2,]
       8
         10 12
, , 3
    [,1] [,2] [,3]
[1,] 13
           15 17
[2,]
    14
          16 18
```

## [2,] 20 22 24

0.3.4.4 Lists

[,1] [,2] [,3]

, , 4

[1,]

Lists are R objects that can contain multiple components of different data types, data structures, and dimensions.

```
names
 [1] "Marshall" "Ruby"
                            "Peppa"
                                       "George"
                                                  "Suzy"
                                                              "Danny"
 [7] "Pedro"
                                       "Ryder"
                                                  "Max"
                                                              "Chase"
                "Rebecca"
                            "Rubble"
grades_1
 [1] 75 76 77 78 79 80 81 82 83 84
list.1 <- list(name = names, grade = grades_1, random_num = 9) # create a list with 3 components</pre>
list.1
```

```
[1] "Marshall" "Ruby"
                            "Peppa"
                                        "George"
                                                   "Suzy"
                                                              "Danny"
 [7] "Pedro"
                "Rebecca"
                            "Rubble"
                                        "Ryder"
                                                   "Max"
                                                               "Chase"
$grade
 [1] 75 76 77 78 79 80 81 82 83 84
$random_num
[1] 9
names(list.1)
                  "grade"
[1] "name"
                               "random_num"
To select from a list, you can keep using index numbers with square brackets [], or you can use the extractor
operator $.
              # create a new list with only the 1st component from list.1
list.1[1]
$name
 [1] "Marshall" "Ruby"
                            "Peppa"
                                        "George"
                                                   "Suzy"
                                                              "Danny"
 [7] "Pedro"
                                                   "Max"
                                                               "Chase"
                "Rebecca"
                            "Rubble"
                                        "Ryder"
list.1[[1]]
              # extract all elements from the 1st component of list.1 (i.e. the name vector)
 [1] "Marshall" "Ruby"
                            "Peppa"
                                        "George"
                                                   "Suzy"
                                                               "Danny"
 [7] "Pedro"
                "Rebecca"
                            "Rubble"
                                        "Ryder"
                                                   "Max"
                                                              "Chase"
list.1$name
              # extract all the elements from the component named "name" from list.1
 [1] "Marshall" "Ruby"
                            "Peppa"
                                        "George"
                                                   "Suzy"
                                                              "Danny"
 [7] "Pedro"
                "Rebecca"
                            "Rubble"
                                        "Ryder"
                                                   "Max"
                                                               "Chase"

#### 0.3.4.5 Data Frames

A data frame is a list whose elements are equal-length vectors, and vectors can be different data types. Basically, a

```
data frame is a limited version of a list, or a flexible version of a matrix. In a data frame, vectors/variables can be
different types, but the length needs to be the same.
df1 <- data.frame(Name = names[1:10], Grade = grades_1)</pre>
df1
       Name Grade
1 Marshall
                75
2
       Ruby
                76
               77
3
      Peppa

## 0.4 R Packages

To extend the capabilities of R, various packages are developed to handle different tasks: data manipulation, analysis, and visualization.

## 0.4.1 Base Packages

The base packages providing basic functions and datasets are pre-included with R installation. For example, the package *datasets*, which provides a collection of datasets.

- Try data(), which returns the list of datasets within this package.
- To load one of the listed datasets, e.g. mtcars, type data(mtcars). This dataset provides statistics from road tests on multiple models of cars.

## 0.4.2 Contributed Packages

Many other contributed packages, designed to implement specific operations, are not included with R by default. To utilize these packages, we need to install and load them individually.

- Install a package, type install.packages("tidyverse")
- Load the installed package, type library(tidyverse)

## Warning

When installing, the package names must be in quotes " ". When loading, they are not necessary.

After loading the package, we can use the functions in tidyverse. tidyverse is a collection of packages, such as dplyr and tidyr for data manipulation, ggplot2 for data visualization, lubridate for processing time-series data.

• Example with select from dplyr, type ?select first to see the R Documentation for this function.

```
library(tidyverse)
data(mpg)
              # new dataset mpg also comes with tidyverse
              # head() displays the first 6 observations of a dataset
head(mpg)
# A tibble: 6 x 11
  manufacturer model displ year
                                    cyl trans
                                                    drv
                                                                   hwy fl
                                                                             class

See how packages simplify the code and make it more intuitive. More details about *tidyverse* will be discussed in Lab 2.

## 0.5 R Script

R script is simply a text file containing a set of commands and comments, which allows you to save, edit, and execute your code. To create an R script, in the top toolbar, select File > New File > R Script.

Opening an R script creates a new pane to your RStudio, the **Source** pane. In this pane, you can edit and save your code. To run your code, you can hold *Ctrl* and press *Enter*, or click the Run button. This will run through your entire R script, or your selected lines of code.

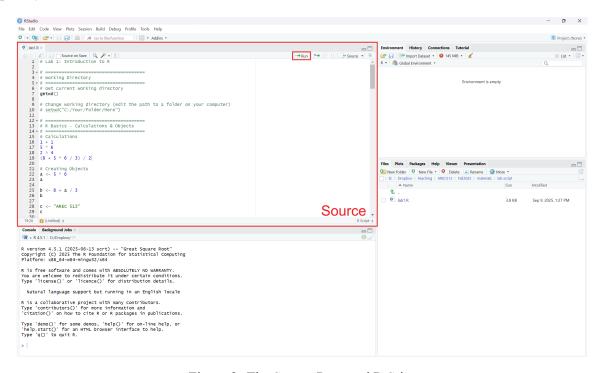

Figure 2: The Source Pane and R Sript

## Note

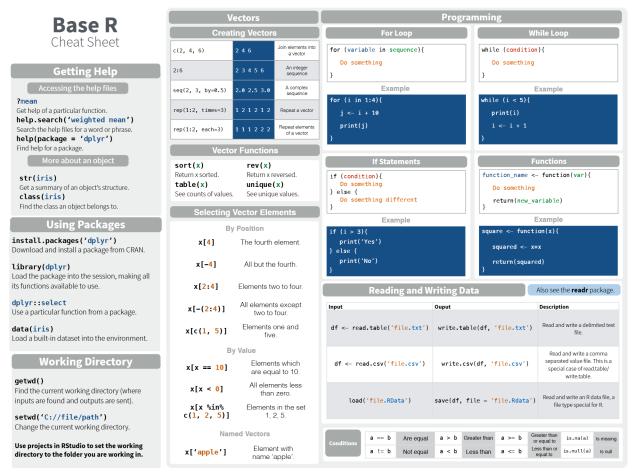

All lines entered in an R script are interpreted as code to be run by R, unless they begin with # (Shift + 3). Using # is useful for documenting and explaining your code, or for temporarily disabling sections of code.

#### 0.6 Useful Resources

This section lists some useful resources for your exploration of R.

## 0.6.2 An Introduction to R

An Introduction to R, by Venables, W. N., Smith, D. M., & R Development Core Team

## 0.7 Exercise

Load the dataset "mpg" and work through the exercises below. Note, "mpg" is included in the tidyverse package, so you will need to load the package first.

- 1. Calculate the **mean**, **range**, **minimum**, and **maximum** of the variable "hwy" across all models. Then, combine these statistics into one vector. (Tip: look up the RDocumentation for the functions mean, range, min, and max).
- 2. Since "hwy" is measured in miles per gallon, create a new variable in mpg that expresses "hwy" in litres per 100 km.
- 3. Identify the models of cars that are most fuel-efficient. Which classes of cars are least fuel-efficient? (Tip: to remove duplicates, use the function unique).
- 4. Compute the quantiles of "hwy". Can you also calculate the tertiles instead? (Tip: look up for the RDocumentation for the function quantile).
- 5. Now, based on the tertiles you calculated, assign "least efficient", "medium", and "most efficient" labels to all models. Try using both base R indexing functions and the function ifelse.
